Queen bee

Article Talk

From Wikipedia, the free encyclopedia

For other uses, see Queen bee (disambiguation).

A **queen bee** is typically an adult, mated female (gyne) that lives in a colony or hive of h bees. With fully developed reproductive organs, the queen is usually the mother of mos all, of the bees in the beehive.[1] Queens are developed from larvae selected by worker and specially fed in order to become sexually mature. There is normally only one adult, queen in a hive, in which case the bees will usually follow and fiercely protect her.

The term "queen bee" can be more generally applied to any dominant reproductive fem a colony of a eusocial bee species other than honey bees. However, as in the Brazilian stingless bee (*Schwarziana quadripunctata*), a single nest may have multiple queens or dwarf queens, ready to replace a dominant queen in case of a sudden death.[2]

Development [edit]

During the warm parts of the year, female "worker" bees leave the hive every day to col nectar and pollen. While male bees serve no architectural or pollinating purpose, their p function (if they are healthy enough) is to mate with a queen bee. If they are successful, fall to the ground and die after copulation. Any fertilized egg has the potential to become queen. Diet in the larval stage determines whether the bee will develop into a queen or

worker. Queens are fed only royal jelly, a protein-rich secretion from glands on the heads of young workers. larvae are fed bee bread which is a mixture of nectar a bee larvae are fed some royal jelly for the first few day hatching but only queen larvae are fed the jelly exclusi result of the difference in diet, the queen will develop in mature female, unlike the worker bees.[3]
